# 1 Introduction

## 2 Classes and methods

## 3 Post-processing

### 3.1 Mean

`m = pygpc.mean(C)` – calculates the mean of the  $N_o$  expanded output variables

---

<b>Parameter</b>	<b>C</b>	<i>numpy array (2D), size: <math>[N_c \times N_o]</math></i> $N_c$ gpc coefficients for each $N_o$ expanded output variable
<b>Returns</b>	<b>y</b>	<i>numpy array (1D) size: <math>[1 \times N_o]</math></i> mean

---

### 3.2 Standard deviation

`s = pygpc.std(C)` – calculates the standard deviation of the  $N_o$  expanded output variables

---

<b>Parameter</b>	<b>C</b>	<i>numpy array (2D), size: <math>[N_c \times N_o]</math></i> $N_c$ gpc coefficients for each $N_o$ expanded variable
<b>Returns</b>	<b>s</b>	<i>numpy array (1D) <math>[1 \times N_o]</math></i> standard deviation

---

### 3.3 Sobol indices

`S, s_idx = pygpc.sobol(g, C)` – calculates the unnormalized Sobol indices of the  $N_o$  expanded output variables

---

<b>Parameter</b>	<b>g</b>	<i>object</i> gpc object
	<b>C</b>	<i>numpy array (2D), size: <math>[N_c \times N_o]</math></i> $N_c$ gpc coefficients for each $N_o$ expanded output variable
<b>Returns</b>	<b>S</b>	<i>numpy array (2D), size: <math>[N_s \times N_o]</math></i> Unnormalized sobol indices usually: normalization with respect to variance $S/\sigma^2$ sorted in descending order (w.r.t. first column only)
	<b>s_idx</b>	<i>list of numpy arrays, length: <math>N_s</math></i> List of corresponding variable combinations of sobol indices in rows of $S$

---

### 3.4 Global derivative based sensitivity coefficients

`G = pygpc.globalsens(g, C)` – calculates the global derivative based sensitivity coefficients of the  $N_o$  expanded output variables

---

<b>Parameter</b>	<b>g</b>	<i>object</i> gpc object
	<b>C</b>	<i>numpy array (2D), size: <math>[N_c \times N_o]</math></i> $N_c$ gpc coefficients for each $N_o$ expanded output variable
<hr/>		
<b>Returns</b>	<b>G</b>	<i>numpy array (2D), size: <math>[d \times N_o]</math></i> Sensitivity indices for each of the $d$ random input and $N_o$ output variables

---

### 3.5 Local sensitivity coefficients

`L = pygpc.localsens(g, C)` – calculates the global derivative based sensitivity coefficients of the  $N_o$  expanded output variables

---

<b>Parameter</b>	<b>g</b>	<i>object</i> gpc object
	<b>C</b>	<i>numpy array (2D), size: <math>[N_c \times N_o]</math></i> $N_c$ gpc coefficients for each $N_o$ expanded output variable
	<b><math>\xi</math></b>	<i>numpy array (1D), size: <math>[1 \times d]</math></i> coordinates in normalized variable space to evaluate local sensitivity in coordinate space: $\beta(a, b, p, q): [a, b] \rightarrow [-1, 1]$
<hr/>		
<b>Returns</b>	<b>L</b>	<i>numpy array (2D), size: <math>[d \times N_o]</math></i> Sensitivity indices for each of the $d$ random input and $N_o$ output variables

---
